Multiple Ocular Dermoids

A 22-year-old woman presented with several masses in her right eye that had been present since birth (Fig 1). The vascularized masses were surrounded by deep corneal opacities. The patient had no systemic abnormalities. Excision and deep anterior lamellar keratoplasty were performed (Fig 2). The diagnosis of multiple ocular dermoids was confirmed by histopathology, which showed keratinized squamous epithelium and fibrous connective tissue (Figs 3–4).
